

A Tailored Anti-Forensic Technique for Digital Image Applications

S.Manimurugan

Athira B.Kaimal

ABSTRACT

The influence of digital images on modern society is incredible, image processing has now become a significant component in almost all the areas. But storing images in a safe and sound way has become very complicated. Sometimes, for processing we can only use raster bitmap format. Therefore processing of such images should be carried out without knowledge of past processing on that image. Even though many image tampering detection techniques are available, the number of image forgeries is increasing. Therefore it is important to find the weaknesses of offered detection methods to prevent further forgeries. In this paper, a new approach is designed to prevent the bitmap compression history. Then it also explains how this can be used to perform unnoticeable forgeries on the bitmap images. It can be done by the estimation, examination and alteration in the transform coefficients of image. The existing methods for identification of bitmap compression history are JPEG detection and Quantizer estimation. The JPEG detection is used to find whether the image has been previously compressed. But the proposed method indicates that proper addition of noise to an image's transform coefficients can adequately eliminate quantization artifacts which act as indicators of JPEG compression. Using the proposed technique the modified image will appear to have never been compressed. Therefore this technique can be used to cover the history of operations performed on the image in the past and there by rendering several forms of image tampering.

Keywords

JPEG compression, Image history, Image coefficients, Digital forensics, Anti-forensics

1. INTRODUCTION

In some situations, images are processed as bitmaps without any information of former processing. It typically happens when we use image data as a bitmap without other information. For example, imaging in operational systems may receive a bitmap image with instructions for rendering it at a particular size and position, but without further information. The image may have been already processed and compressed. But they may not be visually detectable. Photos are usually stored as raster as they contain so much complex information that trying to store them as vector would be unreasonably complex. If one wants to ensure that image is rendered it is enviable to realize the artifacts the image might have, i.e., it is desirable to know a bit of the image's "history." Techniques are available to detect manipulations of bitmap images and these make use of the transformation and other coefficient of images[1][21][23].

It will help to find the prior processing informations. But if a forger with good knowledge in the image processing and signal processing area can hide the evidence of compressions and other tampering. Since images have become an important part of visual communication it is important to examine how

much we can trust on the available detection techniques and what all are the weaknesses. To examine the efficiency and to prevent the manipulations of raster bitmap images many techniques are developed by researchers. These techniques are designed to determine a bitmap images compression history. When the image processing units inherit images in raster bitmap format the processing is to be carried without knowledge of past operations that may compromise image quality (e.g., compression). To carry further processing, it is useful to not only know whether the image has been previously JPEG compressed, but to learn what quantization table was used. Consider the case, if one wants to remove JPEG artifacts or for JPEG re-compression, the existing techniques show it can be detected through JPEG detection and Quantizer estimation [1]. To prevent the image forgeries and to detect those researchers have developed a variety of techniques. They states that using the available techniques such as finding blocking signature[1], estimation of quantization table etc, we can find the evidence of JPEG compression [7]and thereby we can identify image forgeries as well as localized mismatches in JPEG block[4][5].

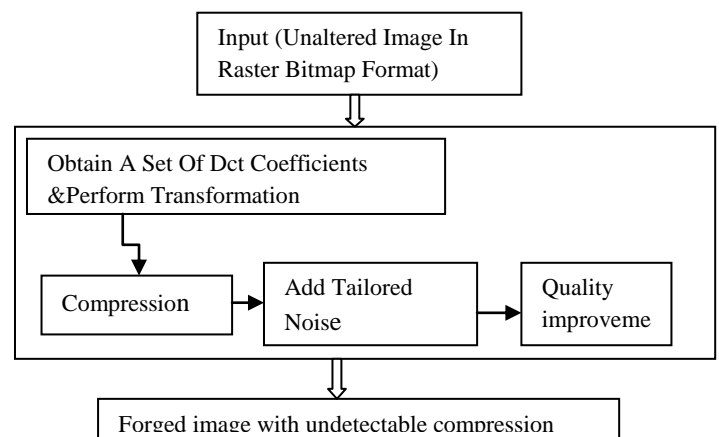

Fig.1.image processing module receives bitmap image. In order to hide the compression history and detectable traces, it first finds the DCT coefficients. Then some transformation and compressions are performed, again DCT coefficients are analyzed to find difference. Add tailored noise to equalize the two DCT values. Apply quality improvement and compress the tampered image.

The extensive availability of photo editing software has made it easy to create visually believable digital image forgeries. To deal with this problem, there has been much recent work in the field of digital image forensics. There has been little work, however, in the field of anti-forensics, which seeks to develop a set of techniques designed to fool current forensic methodologies[22].JPEG compression history of an image can be used to provide evidence of image manipulation[24], deliver information about the camera used to produce an

image, and discover forged areas within a picture [2]. The proper addition of noise to an image's discrete cosine transform coefficients can sufficiently remove quantization artifacts which act as indicators of JPEG compression while introducing an acceptable level of distortion [3][12][18]. Though many existing JPEG detection techniques are capable of detecting a variety of standard bitmap image manipulations, compression histories etc., they do not account for the possibility that new techniques may be designed and used to hide image manipulation evidences. This is particularly important because it calls into question the validity of results indicating the absence of image tampering. It may be possible for an image forger familiar with signal processing to secretly develop new techniques and use them to create undetectable compression and other image forgeries. As a result, several existing techniques may contain unknown vulnerabilities[14][15].

The bitmap images have many advantages, Bitmap files may be easily created from existing pixel data stored in an array in memory. Retrieving pixel data stored in a bitmap file may often be accomplished by using a set of coordinates that allows the data to be conceptualized as a grid. Pixel values may be modified individually or as large groups by altering a palette if present. Bitmap files may translate well to dot-format output devices such as CRTs and printers. In some situations we can only use raster bitmap images for processing. The main problem when we are using raster images is the quality. They can be resized only up to a limited level. Therefore researchers believe that further processing in raster bitmap images will reduce the quality and it can be used as visually identifiable evidence of tampering. But we can develop new techniques which are capable of fooling existing detection methods and capable of improving image quality [3]. Therefore they cannot find any evidence of compression as well as tampering in images[16][17].

2. PROPOSED METHOD

To the best of knowledge the prior work for identifying bitmap compression history is JPEG detection and quantization table estimation [1][8]. In this paper a set of techniques capable of hiding the compression history and evidences of image manipulations are presented. Since most of the techniques involve analyzing the transform coefficients for the variations and blocking artifacts, we propose a new method for removing the detectable traces from images.[19][20] The proposed algorithm can be used to fool most of the existing techniques created for JPEG detection to identify bitmap image compression history. When images undergoes through JPEG compression it will leave some quantization coefficients as evidence [1] [6]. In this paper these are discussed first and then a method is proposed for hiding compression history in the bitmap images.

If one want to ensure that the image is rendered, it is desirable to understand the artifacts that images have. It is also desirable to know a bit of image's history. Existing methods says that we can do this by detecting whether the image has ever been compressed using JPEG standard [1]. In this paper a feasible method for applying anti forensic techniques to hide the JPEG detection for identifying compression history is used. The proposed method can be used to hide the evidence of image compression by removing DCT coefficient fingerprints and by removing blocking artifacts of the image [2][8]. The first step in the identification of the image's compression history is to identify whether the

image has been compressed before or not. But using the tailored anti forensic method we can show an already compressed image as a never compressed image. Therefore it will not give any evidence of compression. It assumes that if there is no compression the pixel Differences across blocks should be similar to those within blocks. We find the differences using DCT coefficients. Let X represents the blocks of image. For applying our method we need to calculate the coefficients of each block before and after compression. First the image is divided into N number of blocks. For each block X (i, j) we compute the coefficients of blocks and that of pixels in each block.

We are considering two blocks. Let X1 be the first block and X2 be the second one. Consider

$$X1(i,j)=\{a1,a2,a3,a4\} \quad (1)$$

$$\text{and } X2(i,j)=\{b1,b2,b3,b4\} \quad (2)$$

where {a1,a2,a3,a4} and {b1,b2,b3,b4} are following two set of pixel values The first set represents the pixels inside block X1 and second represents the pixels inside block X2. We have to find the DCT coefficients of these two blocks and given pixels before and after compression. Let D1 represents the set of coefficients before performing compression and let D1' be the set of transform coefficients after transformation or compression.

We have to find the difference between D1 and D1'. (2) and it is represented as T.

$$T=\sum_n |D1(n)-D1'(n)| \quad (3)$$

When someone try to detect the history of compression this T value is used as the evidence since it shows the difference in coefficient values. Therefore if we are able to hide this difference means we can hide the history of compression and transformations. Using the proposed method we can do this. It is done by adding some noise called tailored dither to the images transform coefficients so that the transform coefficients will match the estimated one. After adding this noise we apply some quality improvement techniques so that the images visual quality of the image will not be affected. Then compression is performed. The final result will be a compressed or forged image with undetectable history of compression and tampering. The proposed technique is explained in the following algorithm

Input :{ image I; stored in raster bitmap format}
Output :{ compressed/forged image with
Undetectable Traces }

Divide image into two blocks

I<-X1+X2

X1<-{a1 a2 a3 a4}

X2<-{b1 b2 b3 b4}

Find D1, D1'

D1<-DCT of X1

D1'<-DCT of X2

Calculate T

$$T<-\sum_n |D1(n)-D1'(n)|$$

Add T+D1'

Apply quality improvement method

Perform compression

3. RESULT AND DISCUSSION

The proposed approach can be used to hide the compression history and to remove JPEG blocking artifacts without affecting the visual quality. For this the tailored anti-forensic approach is applied to five images which are shown from figures 2 to 6. It shows the steps to be performed to implement the new technique .Fig2.1 show the lena image

before and after applying tailored anti-forensic technique. The image (a) represents the original image in bitmap format taken as input. First we analyze the coefficients and find the values then image (b) represents the same image after performing some manipulations. After that we are applying compression and analyze the values and find the difference. Using the value the tailored noise is calculated and which is added to the compressed image so that the values will match with the estimated one. Then we apply some quality improvement techniques to improve the quality. The image (d) shows the final output, and there is no noticeable difference between the input image and the resulting image. Similar way the same technique is applied to the other four images also and the results are obtained as shown. It is clear from the images that by just viewing the images nobody can find out any difference from the original one. That is the images resulted from after applying the proposed technique contains no visual indicators of modification and compression. Since those who want to detect the modifications in the image will not have access to the original image the resulted image cannot be compared against the original one. The modified image will appear as unaltered image.

Fig2.1a)Lena image before compression b)JPEG compressed Image c)applying tailored method & quality improvement d)modified Image after applying tailored method

Fig.2.2.original Input image

Fig.3.2 Original input image

From the resulting images no one can find any difference in the images. But we have to consider the case where forensic techniques are applied for detecting statistical values. As we know the forensic experts can analyze the transform coefficients by comparing the histograms of images. If any difference is found it will be declared as a forged one. Therefore this paper introduces a method to hide the difference between statistical coefficients of histograms of original image and manipulated one. It is capable of fooling forensic researchers. This is done by applying the algorithm explained in the figure 1.2 to the image after modification or compression. Since we have added some tailored noise value to the modified image to match it with the estimated value there will not be much noticeable difference in the histogram coefficients. To examine the efficiency of the proposed method results are shown in the following figure. The figure 8.1 and 8.2 shows the histograms of DCT coefficients of uncompressed bitmap images and that of same images after compression and after applying the tailored technique.

4.2 Original input image

Fig.5.1(a)flower before compression(b)JPEG compressed Image(c) applying tailored method & quality improvement (d) modified Image after applying tailored method

Fig.5.2.Original input image

Analysis of transform coefficients distribution value of the images yields similar results. To verify that the proposed technique can hide the traces of image manipulations the following processing are done on the images. The images store in raster bitmap format are taken as inputs then they are converted in to gray scale images then the coefficient values are identified then the image is compressed using different quality factors. Then the traces of compression is removed by adding some tailored noise to the compressed image and the resulting images are tested using existing detection methods. If no evidence of compression is present then the image is considered as never compressed one.

The summarized results are tabulated in the table.1, after analyzing the coefficients of the original images and tampered one. The values indicate that there is not much difference between the values of original images and tampered images. Since we have added some noise to equalize the coefficients there is a slight difference in the size of image but it is negligible. The error rate is also tabulated and it shows that there is a negligible error rate. Therefore we can consider the proposed method as an effective one to hide the image tampering. The result corresponds to a 86% success rate.

4. CONCLUSION

The contribution of this paper is a tailored anti-forensic technique which is capable of fooling forensic algorithms used to detect compression details and other manipulations on images. Here a reliable method for hiding the compression history is presented. To do this first a generalized frame work is created for identifying and removing traces from images transform coefficients. According to this the traces of image manipulation can be removed by estimating the distribution of transform coefficients before compression then adding some noise to the compressed image so that the modified image's coefficient matches the distribution estimated before compression. It is based on the analysis of transform coefficients of images. The important feature of the proposed technique is its ability to hide the history of compression and manipulations on images. Results shows that it is a reliable one and it will not affect the visual quality of images. Therefore the proposed method is an effective one to hide the image tampering. The result corresponds to a 86% success rate.

5. ACKNOWLEDGMENT

We would like to express our gratitude to all those who gave us the possibility to complete this paper.

AUTHORS PROFILE

Ms.Athira B.Kaimal received the B.E. degree in computer science and engineering in 2011 from the Anna University. She is currently doing M.Tech Research in the area of image Processing at the department Department of computer science and engineering Karunya University.

Dr.S.Manimurugan completed his Bachelor's Degree from Anna University and he received his Master's Degree from Karunya University. His research interests Include Image Processing and Information Security. He was highly commended for his work in Image Processing and Information Security, for which he was honored with a PhD from Anna University
